Eur. J. Biochem. 19:1407-417(1991).
-!- FUNCTION: BINDS THE CAROTENIOL ASTAXANTHIN WHICH PROVIDES THE BLUE.
-: COLORATION TO THE CARAPACE OF THE LOBSTER.
-: SUBUNIT: OLIGOMER; CAN FORM DIMERS (BETA-CRUSTACYANIN); OR
COMPLEXES OF 16 SUBUNITS (ALPHA-CRUSTACYANIN). THERE ARE FIVE
TYPES OF SUBUNITS: Al, A2, A3, C1 AND C2.
-: SUBCELLULAR LOCATION: EXTRACELLULAR, CARAPACE.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Gaps
                                                                                    -- CATALYTIC ACTIVITY: HYDROLYSIS OF TERMINAL, NON-REDUCING BETA-D-GALACTOSE RESIDUES IN BETA-D-GALACTOSIDES.
-- SIMILARITY: BELONGS TO FAMILY 2 OF GLYCOSYL HYDROLASES.

-!- FUNCTION: CATALXZES THE SYNTHESIS OF MEVALONATE. THE SPECIFIC PRECURSOR OF ALL ISOPRENDID COMPOUNDS PRESENT IN PLANTS.
-!- CATALYTIC ACTIVITY: (F) MEVALONATE + COA + 2 NADP(+) = (S)-3-HYDROXX-3-METHYLGIUTARYL-COA + 2 NADPH.
-!- PATHWAY: MEVALONATE BIOSYNTHESIS, PLANT ISOPRENOID BIOSYNTHESIS.
-!- SUBCELLULAR LOCATION: INTEGRAL MEMBRANE PROTEIN. ENDOPLASMIC

ö
           AAR86559-R86596 represent autotaxin (ATX) and fragments of it. This sequence represents the full length protein sequence of the A2058 melanoma cell line ATX protein. ATX is an autocrine motility stimulating protein which is present in cancer cells. ATX stimulates both random and directed migration of melanoma cells. The tumourcus form of ATX is a secreted protein, while the transmembrane bound form is not present in tumour cells. The DANA encoding this sequence can be used to produce the peptide sequences. Antibodies specific for these sequences can be produced, and can be used in cancer diagnosis and therapy. Different sites of localisation of the protein are utilised for diagnosis and prognosis of the stages of tumour progression. The sequences can be used in treatment methods to advantageously block the activity of the secreted form of AXX, while having little effect on the membrane form of
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                GRCFELQEAGPPDCRCDNLCKSYTSCCHDFDELCLKTARGWECTKDRCGEVRNEENACHC 120

                                                                                                                      The present sequence is autotaxin isolated from human melanoma cells. Autotaxin is a glycoprotein cytokine which increases insulin signaling in adipose tissue by producing substrate for adenosine receptors, resulting in inhibition of lipolysis, decreased hepatic gluconeogenesis and serum glucose levels, and increased insulin sensitivity. It also inhibits differentiation of adipocytes. Autotaxin has type I phosphodiesterase, adenosine-5'-triphosphatase (ATPase) and ATP pyrophosphatase activities. Autotaxin and its analogues are used to stimulate glucose uptake by cells, particularly to reduce serum glucose levels for treatment of non-insulin dependent diabetes (NIDDM) in humans, or generally any condition associated with elevated serum levels of glucose, lipid or free fatty acid (e.g. obesity or dyslipidemia).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               /note= "Autotaxin phosphodiesterase catalytic site"

Autotaxin is a givoprotein cytokine which increases insulin signalling in adipose tissue by producing substrate for adenosine receptors, resulting in inhibition of lipolysis, decreased hepatic gluconeogenesis and serum glucose levels, and increased insulin sensitivity. It also inhibits differentiation of adipocytes. Autotaxin has type I phosphoissterase, adenosine-5'-triphosphatase (Arpase) and ArP pyrophosphatase activities.

Autotaxin and its analogues are used to stimulate glucose uptake by cells, particularly to reduce serum glucose levels for treatment of non-insulin dependent diabetes (MIDDM) in humans, or generally any condition associated with elevated serum levels of glucose, lipid or free fatty acid (e.g. obesity or dyslipidemia).

The present sequence is human autotaxin protein.

Autotaxin is a glycoprotein cytokine which increases
insulin signalling in adipose tissue by producing substrate for
adenosine receptors, resulting in inhibition of lipolysis,
decreased hepatic gluconeogenesis and serum glucose levels, and
increased insulin sensitivity. It also inhibits differentiation
of adipocytes. Autotaxin has type I phosphodiesterase, adenosine-5'.
Itriphosphatase (ATPase) and ATP pyrophosphatase activities.
Autotaxin and its analogues are used to stimulate glucose uptake
trathent of non-insulin dependent diabetes (NIDDM) in humans,
or generally any condition associated with elevated serum levels
of glucose, lipid or free fatty acid (e.g. obesity or dyslipidemia).
Transgenic animals that overexpress autotaxin are models for

AAR86559-R86596 represent autotaxin (ATX) and fragments of it. ATX is an autocrine motility stimulating protein which is present in cancer cells. ATX stimulates both random and directed migration of melanoma cells. The tumourcus form of ATX is a secreted protein, while the transmembrane bound form is not present in tumour cells. The cDNA encoding this sequence can be used in a vector, to transform cells. recombinant cells can then be used to produce the peptide sequences. Antibodies specific for these sequences can be produced, and can be used in cancer diagnosis and therapy. Different sites of localisation of the protein are utilised for diagnosis and prognosis of the stages of tumour progression. The sequences can be used in treatment methods to advantageously block the activity of the secreted form of AXT, while having little effect on the membrane form of AXT.
                                                                                                                                                                                                                                                                                                                                                          - used

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             The present sequence is variant (5236T) of rat autotaxin protein. Autotaxin is a glycoprotein cytokine which increases insulin signaling in adipose tissue by producing substrate for adenosine receptors, resulting in inhibition of lipolysis, decreased hepatic gluconeogenesis and serum glucose levels, and increased insulin sensitivity. It also inhibits differentiation of adipocytes. Autotaxin has type I phosphodiesterase, adenosine-5'-triphosphatase activities. Autotaxin and its analogues are used to stimulate glucose uptake by cells, particularly to reduce serum glucose levels for treatment of non-insulin dependent diabetes (NTDNM) in humans.

with elevated serum levels of glucose, lipid or free fatty acid (e.g. obesity or dyslipidemia). Transgenic animals that overexpress autotaxin are models for human metabolic diseases.

Note: The present sequence is not shown in the specification but is derived from rat autotaxin protein sequence found in page 101-104 of sequence listing (AAY71986).
                                                                                                                                                                                                                                                       11 QIISLFTFAVGVSICLGFTAHRIKRAEGWEEGPPTVLSDSPWTNISGSCKGRCFELQEAG

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Autotaxin is adjunced that it is a glycoprotein cytokine which increases insulin signalling in adipose tissue by producing substrate for adenosine receptors, resulting in inhibition of lipolysis, decreased hepatic glucomeogenesis and serum glucose levels, and increased insulin sensitivity. It also inhibits differentiation of adipocytes. Autotaxin has type I phosphodiesterase, adenosine 5'-triphosphatase (ATPASS) and ATP pyrophosphatase activities. Autotaxin and its analogues are used to stimulate glucose uptake by cells, particularly to reduce serum glucose levels for treatment of non-insulin dependent diabetes (NIDDM) in humans, or generally any condition associated with elevated serum levels of glucose, lipid or free fatty acid (e.g. obesity or dyslipideamia). Transgenic animals that overexpress autotaxin are models for human metabolic diseases.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      present sequence is variant ($289T) of rat autotaxin protein.

                                                                                                                                                                                                                                                                                                                                                                                                                                                   The present sequence is variant (R265K) of rat autotaxin protein.

Autotaxin is a glycoprotein cytokine which increases insulin signalling in adipose tissue by producing substrate for adenosine receptors, resulting in inhibition of lipolysis, decreased hepatic gluconeogenesis and serum glucose levels, and increased insulin sensitivity. It also inhibits differentiation of adipocytes.

Autotaxin has type I phosphodiesterase, adenosine-5'-triphosphatase (ATPase) and ATP pyrophosphatese activities. Autotaxin and its analogues are used to stimulate glucose uptake by cells, particularly to reduce serum glucose levels for treatment of non-insulin dependent clabetes (MIDDM) in humans, or generally any condition associated with elevated serum levels of glucose, lipid or free fatty acid (e.g. obesity or dyslipidemia). Transgenic animals that overexpress outcaxin are models for human metabolic diseases.

Note: The present sequence is not shown in the specification but is derived from rat autotaxin protein sequence found in
                                                                                                                                                                                                                                                                                                                                                                                           and

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        glycoprotein cytokine which increases insulin signalling in adipose tissue by producing substrate for adenosine signalling in adipose tissue by producing substrate for adenosine receptors, resulting in inhibition of lipolysis, decreased heptic glucomeogenesis and serum glucose levels, and increased insulin sensitivity. It also inhibits differentiation of adipocytes. Autotaxin has type I phosphodiesterase, adenosine 5'-triphosphatase (Arpass) and Arp pyrophosphates activities. Autotaxin and its analogues are used to stimulate glucose uptake by cells, particularly to reduce serum glucose levels for treatment of non-insulin dependent diabetes (NIDDM) in humans, or generally any condition associated with elevated serum levels of glucose, lipid or free fatty acid (e.g. obesity or dyslipidemia). Transgenic animals that overexpress autotaxin are models for human metabolic diseases.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      PPDCRCDNLCKSYTSCCHDFDELCLKTARGWECTKDRCGEVRNEENACHCSEDCLARGDC 130

                                                                                                                                                                                                                                                                                                                                                                    The present sequence is variant (A194V) of rat autotaxin protein.

Autotaxin is a glycoprotein cytokine which increases insulin
signalling in adipose tissue by producing substrate for adenosine
receptors, resulting in inhibition of lipolysis, decreased hepatic
gluconeogenesis and serum glucose levels, and increased insulin
sensitivity. It also inhibits differentiation of adipocytes.

Autotaxin has type I phosphodissterase, adenosine-5'-triphosphatase
(ATPase) and ATP pyrophosphatase activities. Autotaxin and its
analogues are used to stimulate glucose uptake by cells, particularly
to reduce serum glucose levels for treatment of non-insulin dependent
clabetes (NIDDM) in humans, or generally any condition associated
with elevated serum levels of glucose, lipid or free fatty acid
(e.g. obesity or dyslipidemia). Transgenic animals that overexpress
                                                                                                                                                                                                                                                                                       New autotaxin proteins, useful e.g. for treating diabetes mellitus and obesity, stimulate glucose uptake by cells and inhibit lipolysis -

                                                                                                                       Autotaxin is a glycoprotein cytokine which increases insulin signalling in adipose tissue by producing substrate for adenosine receptors, resulting in inhibition of lipolysis, decreased hepatic gluconeogenesis and increased hepatic gluconeogenesis and serum glucose levels, and increased hepatic sensitivity. It also inhibits differentiation of adipocytes.

Autotaxin has type I phosphodiesterase, adenosine-5'-triphosphatase (ATPase) and ATP pyrophosphates activities. Autotaxin and its analogues are used to stimulate glucose uptake by cells, particularly to reduce serum glucose levels for treatment of non-insulin dependent diabetes (NIDDM) in humans, or generally any condition associated with elevated serum levels of glucose, lipid or free fatty acid (e.g. obesity or dyslipidemia). Transgenic animals that overexpress autotaxin are models for human metabolic diseases.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   71 PPDCRCDNLCKSYTSCCHDFDELCLKTARGWECTKDRCGEVRNEENACHCSEDCLARGDC 130

AAR86559-R86596 represent autotaxin (ATX) and fragments of it. This sequence represents the full length protein sequence of the teratocarchinoma N-tera 2D1 ATX protein. ATX is an autocrine motility stimulating protein which is present in cancer cells. ATX stimulates both random and directed migration of melanoma cells. The tumourous form of ATX is a secreted protein, while the transmembrane bound form is not present in tumour cells. The cDNA encoding this sequence can be used in a vector, to transform cells. The recombinant cells can then be used to produce the peptide sequences. Antibodies specific for these sequences can be produced, and can be used in cancer diagnosis and therapy. Different sites of localisation of the protein are utilised for diagnosis and prognosis of the stages of tumour progression. The

This sequence is designated as nucleotide pyrophosphatase.
This sequence is designated as nucleotide pyrophosphatase.

(PD-lalpha), Autotaxin is a glycoprotein cytokine increases insulin signalling in adipose tissue by producing substrate for adenosine receptors, resulting in inhibition of lipolysis, decreased hepatic gluconeogenesis and serum glucose levels, and increased insulin sensitivity. It also inhibits differentiation of adipocytes.

Autotaxin has type I phosphatase activities. Autotaxin and its analogues are used to stimulate glucose uptake by cells, particularly to reduce serum glucose levels for treatment of non-insulin dependent diabetes (NIDDM) in humans, or generally any condition associated with elevated serum levels of glucose, lipid or free fatty acid (e.g. obesity or dyslipidemia). Transgenic animals that overexpress autotaxin are models for human metabolic diseases.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         New autotaxin proteins, useful e.g. for treating diabetes mellitus and obesity, stimulate glucose uptake by cells and inhibit lipolysis -

AAR86559-R86596 represent autotaxin (ATX) and fragments of it. ATX is an autocrine motility stimulating protein which is present in cancer cells. ATX stimulates both random and directed migration of melanoma cells. The tumourous form of ATX is a secreted protein, while the transmembrane bound form is not present in tumour cells. The cDNA encoding this sequence can be used in a vector, to transform cells. The recombinant cells can then be used to produce the peptide sequences. Antibodies specific for these sequences can be produced, and can be used in cancer diagnosis and therapy. Different sites of localisation of the protein are utilised for diagnosis and prognosis of the stages of tumour progression. The sequences can be used in treatment methods to advantageously block the activity of the secreted form of AXT, while having little effect on the membrane form of AXT.

```

an autocrine motility stimulating protein which is present in cancer cells. ATX stimulates both random and directed migration of melanoma cells. ATX stimulates both random and directed migration of melanoma transmembrane bound form of ATX is a secreted protein, while the transmembrane bound form is not present in tumour cells. The cDNA encoding this sequence can be used in a vector, to transform cells. The recombinant cells can then be used to produce the peptide sequences. Antibodies specific for these sequences can be produced, and can be used in cancer diagnosis and therapy. Different sites of localisation of the protesn are utilised for diagnosis and prognosis of the stages of tumour progression. The sequences can be used in treatment methods to advantageously block the activity of the secreted form of AXT, while having little effect on the membrane form of AXT.
